### Abstract

This study aims to investigate the relationship between perfectionism and hopelessness levels among university students studying in Turkey. It also examines how these psychological constructs relate to certain demographic variables, particularly gender. This study was initiated in response to the increasing need to understand the psychological effects of these traits within the context of Turkish higher education, where students often face multidimensional stressors such as academic pressure, career anxiety, and sociocultural expectations. By focusing on this group, the study aims to provide culturally informed insights into how perfectionism relates to hopelessness, and to contribute to the development of targeted psychological interventions for student populations. The sample consisted of 235 university students (81 male and 154 female) who voluntarily participated in an online survey. Data collected from the participants were analyzed using SPSS statistical software. The findings revealed no statistically significant relationship between adaptive perfectionism and hopelessness levels ( $p > .05$ ). This result suggests that having high standards and striving for order may not necessarily be associated with a negative emotional state such as hopelessness. On the other hand, a statistically significant negative correlation was found between maladaptive perfectionism and hopelessness ( $r = -0.157, p < .05$ ), indicating that individuals who experience higher levels of dissatisfaction and internal conflict are more likely to feel hopeless. Overall, these results emphasize the importance of distinguishing between different dimensions of perfectionism when addressing the psychological needs of university students. The findings highlight that maladaptive perfectionism may contribute to an increased risk of hopelessness, whereas adaptive perfectionism might not have the same detrimental effect. Therefore, psychological support programs designed to reduce hopelessness and promote well-being among students should take these differences into account. Future research should continue to explore how perfectionism functions within different cultural settings and whether its dimensions serve as risk or protective factors in relation to various aspects of mental health.

## Introduction

Hope is a form of belief that a result can be achieved and that there can be a change in one's conditions and situation with help. One of the definitions in the literature about hope belongs to Rideout and Montemuro (1986) and they defined hope as the expectation of completing a goal related to the future. At this point, hopelessness is explained as a

<sup>1</sup> Master student, Istanbul Aydın University, Department of Psychology, Clinical Psychology Master's Program, Istanbul, Türkiye. E-mail: [busecalkan@stu.aydin.edu.tr](mailto:busecalkan@stu.aydin.edu.tr) ORCID: 0000-0002-4125-7780

negative expectation to fulfill and finalize a goal. A general definition was made for both hope and hopelessness as a reflection of the possibilities of achieving one's future goals (Melges, 1969). Hopelessness is the state of mind that arises as a result of an individual's inability to maintain positive expectations for the future or the weakening of these expectations. While hope involves the confidence that good things will happen in the future (TDK, 2025), hopelessness is shaped by the loss of this confidence. According to Tönbül (2025), hopelessness is associated with the negative shaping of an individual's expectations or the loss of a sense of control over the future. This process may lead to changes in the way the individual evaluates events and possibilities, so that the individual may believe that the positive developments they expect will not materialize. Beck et al. defined hopelessness as both a motivational and cognitive issue characterized by the presence of negative expectations about the future. In addition, Beck accepts the concept of hopelessness as a basic feature of depression. (Beck et al., 1985). Freud (1917), on the other hand, states that individuals experiencing melancholia have a deep sense of hopelessness and may see themselves as worthless, inadequate and morally defective. According to him, this hopelessness is linked to a loss that the individual is not consciously aware of but which occupies an important place in his/her psychological structure. Although the individual cannot fully comprehend this loss at the level of consciousness, he/she feels an intense sense of helplessness and exhaustion in his/her inner world. Freud's approach shows that hopelessness may be related not only to recognized disappointments but also to unconscious processes of mourning and loss.

The concept of perfectionism is defined by Burns (1980) as a condition associated with the desire to constantly move from one's current position to a higher position with a rhythm that disrupts functionality and to see self-esteem as a quality gained only by evaluating whether these goals are achieved or not. In connection with this, individuals with perfectionism have problems in existing with the feelings and thoughts that arise as a result of failing and staying in this position, and they cannot provide the value of themselves through another quality. As a result of cognitive distortions, they may have difficulties in social relationships because thoughts about whether they will be accepted by other people if they are not perfect may have become their basic beliefs.

According to Freud's theory, perfectionism is closely related to the superego, which is fed by the strict moral standards internalized by the individual. The oppressive structure of the superego may cause the individual to feel the obligation to be better and to see his/her current situation as inadequate (Freud, 1920). This situation may lead to an intense process of disappointment and self-criticism if the individual fails to reach the expectations within himself/herself. As Freud states in *The Self and the Id* (1920), the superego not only punishes mistakes, but also considers the individual's not being perfect enough as a deficiency.

According to the literature, perfectionism can be considered to be linked to hopelessness. Individuals who constantly pursue unattainable ideals may tend to devalue their own achievements and over time may feel a sense of hopelessness. As Freud explains in his text *Mourning and Melancholia* (1917), hopelessness is often associated with a loss that operates on an unconscious level. For the perfectionist, this loss may be disappointment in the face of unattainable goals. As a result, perfectionism, which develops under the pressure of the superego, may cause the individual to develop harsh criticism towards himself/herself and as a result, experience the feeling of hopelessness more intensely.

The concept of perfectionism is examined in 2 sub-dimensions: positive perfectionism and negative perfectionism. Frost et al. (1990) stated that positive perfectionism allows individuals to see success and personal development as an intrinsic reward. This approach is linked to a healthy level of self-esteem and a sense of control. Positive perfectionism also plays an important role in managing stress and celebrating achievements in a satisfying way. On the contrary, Frost uses negative perfectionism in the APS Perfectionism Scale as a tool to measure individuals' criticism of themselves and others, their fear of failure, and the inner guilt and anxiety associated with these fears.

There is no study examining the relationship between perfectionism and hopelessness levels of university students in our country. In this respect, we think that it will contribute to the literature. Examining the relationship between perfectionism and hopelessness levels of students studying in higher education institutions with correlation analysis will

contribute to both theoretical and applied psychology. For individuals studying at higher education level, these years are conceptualized as a transition period in which individuals face a wide variety of stress factors in academic, social and developmental areas (Arnett, 2016). Examining psychosocial variables in this period is important for the psychological and academic functionality of students.

Perfectionist personality structure, especially in maladaptive modes, has been included in studies as a transdiagnostic risk factor that negatively affects students' mental health levels (Hewitt, 2007). Fear of failure, overly critical self-evaluation and rigid high standards increase the stress level of the person in the academic field and create a cognitive ground for hopelessness as it becomes chronic (Stoeber, 2006). Accordingly, a comprehensive analysis of these two variables is considered to be an important necessity for early detection of psychopathological symptoms and development of preventive intervention strategies.

Some of the university students in Turkey continue their education with multifactorial stressors such as uncertainty about the future, career uncertainty, socioeconomic problems and cultural expectations in addition to their academic requirements (Eskin, 2016). Under these complex conditions, examining the effect of cognitions with perfectionist and hopelessness themes is expected to provide a scientific basis for optimizing psychosocial support mechanisms and intervention protocols within the university accordingly. In addition, the results of this research will enable academic staff and university administration to assess the psychoeducational needs of their students and develop evidence-based strategies.

### **Problem of Study**

Is there a relationship between perfectionism and hopelessness levels of university students?

**Hypothesis:** There is a significant negative relationship between university students' hopelessness levels and their perfectionism levels.

- It is assumed that the students who contributed to the research answered the questionnaires sincerely and correctly.
- It is assumed that the data collection tool adequately measures the researched topic and is sufficient.
- It is assumed that the findings obtained represent the population.

### **Method**

#### **Research Model**

The study was based on the relational survey model based on the descriptive research model.

#### **Sample**

The participants of this study were undergraduate students currently enrolled in various universities across Turkey. A total of 235 students aged between 19 and 25 years participated in the study. This age range was selected to reflect the typical span of undergraduate education in Turkey. Participants were reached through an online survey distributed via Google Forms. To be included in the study, participants had to be currently enrolled in an undergraduate program, between 19–25 years of age, and willing to participate voluntarily. Students who failed to complete the survey or responded with extreme response patterns were excluded from the final dataset. Prior to participation, individuals were informed about the purpose of the study and assured of the anonymity and confidentiality of their responses. All participants provided informed consent electronically. Data collection was conducted via Google Forms, and duplicate or incomplete submissions were eliminated during data cleaning.

**Table 1.** Frequency Table of Participants

|                    | <i>f</i> | <i>%</i> | <i>Valid %</i> | <i>Cumulative %</i> |
|--------------------|----------|----------|----------------|---------------------|
| Gender             |          |          |                |                     |
| Male               | 81       | 34.5     | 34.5           | 34.5                |
| Woman              | 154      | 65.5     | 65.5           | 100.0               |
| Age group          |          |          |                |                     |
| 19 years old       | 38       | 16.2     | 16.2           | 16.2                |
| 20 years old       | 81       | 34.5     | 34.5           | 50.6                |
| 21 years old       | 59       | 25.1     | 25.1           | 75.7                |
| 22 years old       | 26       | 11.1     | 11.1           | 86.8                |
| 23 Years and above | 31       | 13.2     | 13.2           | 100                 |
| Total              | 235      |          |                |                     |

The results of the frequency analysis conducted to examine the distribution of participants according to gender and age are presented in Table 1. According to the results of the analysis, 34.5% of the participants were male (N=81) and 65.5% were female (N=154). When the distribution of the participants according to age was analyzed, 16.2% were 19 years old (N=38), 34.5% were 20 years old (N=81), 25.1% were 21 years old (N=59), 11.1% were 22 years old (N=26) and 13.2% were 23 years old and above (N=31).

### Data Collection and Analysis

Sampling was carried out using a randomization technique. Approval to use the measurement tools in this study was obtained from the Ethics Committee for Social and Human Sciences at Istanbul Aydın University, with the official decision dated 17.10.2024 (Decision No: 2024/11). After the scales were applied digitally through Google Forms, the data were entered into the IBM SPSS Statistics program. Independent sample t-test was used to examine perfectionism and hopelessness variables according to gender. Pearson Correlation Analysis was used to examine the relationship between perfectionism and hopelessness level. Demographic Information Form, Beck Hopelessness Scale and APS Perfectionism Scale were used as data collection tools.

### Personal Information Form

The "Demographic Information Form", which was prepared by the researcher and included questions on gender, socio-economic status, and education level, was used to collect information about the demographic characteristics of the sample participants.

### Beck Hopelessness Scale (BHS)

It is a tool developed by Beck et al. (1974) and aims to measure the expectations of adolescents and adults about the future. The scale contains 20 items and the answers given as "Yes" or "No" to each item are evaluated as 0 or 1 point. Thanks to this structure, the total score of the individual varies between 0 and 20; higher scores indicate an increased level of hopelessness. The scale includes questions such as "The future seems to be full of unpleasantness rather than pleasant things for me", "I do not hope that I will be able to achieve the things I really miss", "The future seems blurry and uncertain to me". In the validity and reliability study conducted by Durak (1994), it was reported that the Cronbach's alpha reliability coefficient of the scale was 0.85 and the item-test correlations reached the lowest value of 0.31 and the highest value of 0.67

### APS Perfectionism Scale

The scale, originally introduced by Slaney et al. (2001), was designed to assess individuals' perfectionist tendencies by distinguishing between their adaptive and maladaptive components. The scale collects participants' evaluations with Likert-type response options ranging from 1 to 7. It was determined that the original form did not adequately reflect the negative dimensions of perfectionism, and for this reason, it was revised by increasing the number of items and adding a new "conflict" subscale. Factor analyses and validity studies revealed that the revised scale reliably measured congruent and incongruent perfectionism (Slaney et al., 2001). As a result of the revisions, the scale had a 4-factor structure. While

the sub-dimensions of "high standards" and "order" explain positive perfectionism, the dimensions of "conflict" and "dissatisfaction" explain negative perfectionist traits. Questions 6, 11, 13, 17, 20, 23 in the scale such as 'I am never satisfied with my achievements', 'Even the things I do best never seem enough to me' are included in the 'dissatisfaction' dimension. Questions 3, 9, 15, 23 such as 'I rarely reach my standards with my performance', 'I think what I do is good enough. Questions numbered 3,9,15,16, 19, 21 such as 'I am an organized person', 'Tidiness and order are important to me' are included in the 'order' sub-dimension and questions numbered 1,5,8, 12, 14, 18, 22 such as 'I expect the best from myself', 'I try to do the best in everything I do' belong to the 'High Standards' sub-dimension.

## Results

**Table 2.** Descriptive Statistics of the Scales

|                           | <i>N</i> | <i>Range</i> | <i>Lowest</i> | <i>Highest</i> | $\bar{x}$ | <i>ss</i> | <i>Siv.</i> | <i>Wed.</i> |
|---------------------------|----------|--------------|---------------|----------------|-----------|-----------|-------------|-------------|
| Hopelessness              | 235      | 16           | 23            | 39             | 29.78     | 2.04      | -.222       | 2.685       |
| APS Perfectionism         | 235      | 129          | 32            | 161            | 100.30    | 23.81     | -.099       | -.165       |
| Adaptive Perfectionism    | 235      | 63           | 14            | 77             | 54.90     | 12.51     | -.654       | 0.22        |
| Maladaptive Perfectionism | 235      | 67           | 17            | 84             | 45.40     | 14.77     | .184        | -.474       |
| Valid N                   | 235      |              |               |                |           |           |             |             |

According to the results of the analysis, the mean score of the participants from the Beck Hopelessness Scale is  $\bar{x}=29.78$  and the standard deviation is  $ss=2.04$ . The mean total score of the participants on the APS Perfectionism Scale is  $\bar{x}=100.30$  and the standard deviation is  $ss=23.81$ . The mean score of the participants from the congruent perfectionism dimension, which is the sub-dimension of the APS Perfectionism scale, is  $\bar{x}=54.90$ , and the standard deviation is  $ss=12.51$ . The mean score obtained from the other sub-dimension, maladaptive perfectionism, is  $\bar{x}=45.40$ , and the standard deviation is  $ss=14.77$ .

**Table 3.** Pearson Correlation Analysis on the Relationship between Hopelessness and Perfectionism Levels

| Variable      | <i>n</i> | $\bar{X}$ | <i>SS</i> | 1      |
|---------------|----------|-----------|-----------|--------|
| Hopelessness  | 235      | 29.78     | 2.04      | -      |
| Perfectionism | 235      | 100.29    | 23.80     | -.157* |

As a result of the Pearson Correlation Analysis, it was observed that there was a weak negative relationship between individuals' perfectionism levels and their hopelessness levels,  $r = -.157$ ,  $p < .05$ .

**Table 4.** Pearson Correlation Analysis on the Relationship between Hopelessness Levels and Agreeable Perfectionism Levels

| Variable               | <i>n</i> | $\bar{X}$ | <i>SS</i> | 1     |
|------------------------|----------|-----------|-----------|-------|
| Hopelessness           | 235      | 29.78     | 2.04      | -     |
| Adaptive Perfectionism | 235      | 54.89     | 12.51     | -.039 |

No statistically significant result was found in the relationship between the sub-dimension of perfectionism, congruent perfectionism, and hopelessness,  $p > .05$ .

**Table 5.** Pearson Correlation Analysis on the Relationship between Hopelessness Levels and Maladaptive Perfectionism Levels

| Variable                  | <i>n</i> | $\bar{X}$ | <i>SS</i> | 1      |
|---------------------------|----------|-----------|-----------|--------|
| Hopelessness              | 235      | 29.78     | 2.04      | -      |
| Maladaptive Perfectionism | 235      | 45.40     | 14.77     | -.220* |

It was observed that there was a weak negative relationship between the level of maladaptive perfectionism, which is a sub-dimension of perfectionism, and hopelessness,  $r=-.220$ ,  $p<.05$ .

**Table 6.** Independent Sample T Test to Examine the Hopelessness Levels of Individuals by Gender

| Gender | N   | Ort.  | SS   | t     | df  | p    |
|--------|-----|-------|------|-------|-----|------|
| Male   | 81  | 29.67 | 1.85 | -.565 | 233 | .838 |
| Woman  | 154 | 29.83 | 2.13 |       |     |      |

According to the results of the independent t-test, gender did not appear to have a significant effect on students' hopelessness levels.  $t(233) = -.565$ ,  $p>.05$ .

Data analysis indicated a weak inverse correlation between the two variables. However, the main interpretation should be made by considering that perfectionism has 2 different sub-dimensions because a scale with a two-factor structure was applied to express 2 opposite directions. The relationship between congruent perfectionism and maladaptive perfectionism sub-dimensions and hopelessness level was also examined in the study. According to the results obtained, no significant difference was found between adaptive perfectionism and hopelessness levels of university students, while a significant negative relationship was found between maladaptive perfectionism levels and hopelessness levels. Within the scope of the research, an independent sample t-test was applied to examine whether the participants' hopelessness levels differed according to gender and no significant difference was found between genders.

### Discussion

The data obtained at the end of the research show that there is no significant relationship between adaptive perfectionism personality traits and hopelessness levels in university students. This finding is consistent with the literature (Stoeber, 2006). On the other hand, the finding of a negative and statistically significant relationship between maladaptive perfectionism and hopelessness contradicts the expectation in the literature. In the existing research, maladaptive perfectionism is generally explained by a focus on mistakes, a fear of failure, harsh and unconstructive self-criticism, and maladaptive high standards, and is positively associated with various psychopathologies (Hewitt, 2007). Flett (2016) concluded that maladaptive perfectionism showed strong correlations with negative psychological factors such as depression and anxiety in many studies, but the fact that the relationship in the variables mentioned in this study was found in the opposite direction is a unique factor that will make a significant contribution to the literature.

There may be various explanations for this result. First of all, maladaptive perfectionist traits need to be discussed and examined in a cultural context. Wang et al. (2012) stated that this trait may have different meanings according to cultural factors. According to these characteristics, maladaptive perfectionism may have adaptive functions in certain cultures. Compared to European countries, Turkey has a more collectivist structure (Canatan, 2011). In a cultural structure that shows these tendencies and where the success of the individual has a high meaning, perfectionist structures, which are characterized as maladaptive in the literature, may take place in the life of the individual as a protective factor (Kağan, 2011; Baloğlu & Koçak, 2006). This may be one of the explanations that can be made with the data obtained as a result of the analyzes.

Another explanation is that it may be related to psychosocial factors, that is, it may be related to the mediating role of social support mechanisms. Ergene (2018) reported a strong association between social support and increased psychological resilience in the context of Turkish university students. These students may benefit more from various factors such as family and peer support compared to other students.

Another explanation may be related to the unique nature of the academic environment. Students who show perfectionist tendencies in the academic environment may increase their skills such as motivation and goal focus, providing them with a sense of control and a sense of future direction (Stoeber & Otto, 2006). This may function as a factor that reduces hopelessness in societies like our country where the levels of career uncertainty and future anxiety are above average and in low economic conditions (Çelik, 2020).

Additionally, the study found no significant gender differences in terms of perfectionism or hopelessness levels. This outcome suggests that the effects of perfectionism on hopelessness may operate similarly across male and female students in this context. Interestingly, the lack of association between adaptive perfectionism and hopelessness contrasts with some previous findings in the literature, pointing to the potential influence of cultural and contextual factors on the development and impact of perfectionistic traits.

### **Conclusion**

The findings of the analysis suggested a low-level negative correlation between these two variables. However, the main interpretation should be made by considering that perfectionism has 2 different sub-dimensions because a scale with a two-factor structure was applied to express 2 opposite directions. The relationship between adaptive perfectionism and maladaptive perfectionism sub-dimensions and hopelessness level was also examined in the study. According to the results obtained, no significant difference was found between adaptive perfectionism and hopelessness levels of university students, while a significant negative relationship was found between maladaptive perfectionism levels and hopelessness levels. Within the scope of the research, an independent sample t-test was applied to examine whether the participants' hopelessness levels differed according to gender and no significant difference was found between genders.

The data obtained in this study reveals that research strategies should be revised in various aspects in order to examine the relationship between university students' perfectionism and hopelessness levels in more depth. Firstly, diversification of the sample to include individuals with wider and different sociocultural characteristics will increase the validity of the results obtained. Secondly, long-term studies that can reveal changes and interactions over time should be planned instead of the current cross-sectional design. Thus, dynamic changes in perfectionism and hopelessness levels can be better understood. In addition, how the concept of perfectionism interacts with cultural systems and social expectations rather than individual psychological structure should be emphasized.

Another important finding of the study is that there is no significant difference between genders. This shows that the stress factors faced by students are largely similar. Many stressors such as exam anxiety, graduation pressure, economic difficulties in the university environment affect both genders in a similar way. Therefore, it may be more functional to focus on common life experiences rather than gender-based distinctions in planning psychological interventions. In addition, the cultural validity of the measurement tools used in the study should also be taken into consideration. Because some psychological concepts may function differently in different cultural settings. Therefore, it is recommended that the validity and reliability levels of the scales used in this study should be retested in Turkish samples. This study offers new perspectives to researchers in terms of both methodological and practical aspects and shows that perfectionism should be reconsidered in a cultural context.

In the gender variable, which was examined and analyzed among demographic characteristics, no significant difference was found between hopelessness and gender. This result shows that university students are exposed to stressors that are not related to gender. This situation leads us to the conclusion that it may be healthier to design an approach that does not discriminate on the basis of gender in preventive and intervention programs to be carried out regarding hopelessness and covers all students equally.

When analyzed in the context of research methods, the level of cultural sensitivity and construct validity of the measurement tools may also explain this unique finding. It is known that the scales used in the field can show differences in intercultural context (Stallman & Hurst, 2011). Oishi and Sullivan (2005) emphasized that some of the definitions used in this study, such as perfectionism and hopelessness, may not reflect the same phenomenological structure for each country in a cultural context. From this point of view, the negative relationship between these two concepts in university students studying in Turkey may become theoretically meaningful.

The relationship between perfectionism and hopelessness is a relevant topic in contemporary mental health research, particularly among university students who are navigating the developmental challenges of early adulthood. This population often faces increased academic demands, social comparison, and uncertainty about the future—factors that

can exacerbate both perfectionist tendencies and hopeless thoughts. Therefore, exploring how these constructs interact can provide valuable insights into risk and protective mechanisms in young adults.

As a researcher with clinical training and experience working with young populations, I was motivated to investigate this topic due to the rising psychological distress observed among students in academic settings. In the Turkish context especially, students are often burdened with high expectations from family and society, which may intensify the effects of maladaptive perfectionism. I aimed to explore whether this pressure translates into hopelessness, or if certain dimensions of perfectionism could act as coping mechanisms.

The findings of this study suggest that maladaptive perfectionism, while typically associated with negative outcomes, may not increase hopelessness in all cultural settings. This challenges widely held assumptions in the literature and highlights the need for culturally sensitive interpretations of perfectionism. The absence of a significant relationship between adaptive perfectionism and hopelessness further supports the idea that not all perfectionist traits are inherently harmful. These results offer a nuanced understanding of how perfectionism manifests in university students and may help inform interventions aimed at reducing emotional distress in this population.

### **Recommendations**

In future studies, it may be recommended to examine the psychosocial factors that may affect these two variables. On the implementation dimension, the development of mental health interventions and counseling programs for students in universities can increase the practical usefulness of the findings obtained; in this context, experimental studies to measure the effectiveness of interventions will also make important contributions. In the psychosocial support centers of universities, psychoeducation programs should be organized to raise awareness about both adaptive and maladaptive perfectionism tendencies of students and their bases, cultural factors should be taken into consideration while organizing these programs, and it should be taken into consideration that maladaptive perfectionism, which has a protective feature, may not lead to a psychopathology. Finally, retesting the validity and reliability of the scales used in different sample groups would be an important step in terms of updating the measurement tools.

### **Limitations of the Study**

This study has a number of limitations. First, the study data were collected only through a cross-sectional research design. Therefore, it is not possible to comment on the causality of the relationship between perfectionism and hopelessness. How the relationship between the variables develops or changes over time can only be evaluated more accurately with longitudinal studies.

Secondly, the sample group used in the study consists of only 235 students studying at certain universities. This situation limits the generalizability of the findings. Most of the participants may have similar socio-demographic characteristics; therefore, studies that include individuals from different regions, age groups or educational levels are needed.

Third, the self-report questionnaires used in the study may be subject to bias due to the possibility that participants may express themselves differently than they actually are. The social favorability effect may affect the accuracy of responses, especially for scales assessing psychological traits.

In addition, the validity and reliability of the APS Perfectionism Scale and Beck Hopelessness Scale in a cultural context can be considered as limitations. Although these scales have been adapted into Turkish before, it should not be forgotten that cross-cultural differences may affect the way of producing meaning. Characteristics that are conceptually characterized as “maladaptive” or “maladaptive” may be functional in some cultural settings.

Finally, the study only examined the gender variable in terms of demographic differences. However, the effects of other demographic factors such as age, income level, faculty type, academic achievement level on perfectionism and hopelessness are also worth examining. More detailed analyses by taking these factors into consideration will reveal the multidimensional structure of the issue more clearly.

## Acknowledgements

This study was approved by the Ethics Committee of Istanbul Aydın University. I also thank all the university students who participated voluntarily in the data collection process for their contributions.

*Competing interests:* The authors acknowledge that there is no conflict of interest with any institution. *Informed consent:* Informed consent forms were given to all study participants and necessary ethics committee approvals were obtained.

*Funding:* This research did not receive financial support from any governmental, commercial, or non-profit organization.

*Originality Statement:* This manuscript is an original contribution and has not been published before. It is also not being reviewed or considered for publication by any other journal at this time.

*Data Availability:* Data used and generated in this study can be shared by the corresponding author upon justified request.

## Biodata of Authors

Buse Calkan

### Education

Istanbul Aydın University, Bachelor's in Psychology

Istanbul Aydın University, Clinical Psychology Master's Program

### Internships

Intern Psychologist, Bakırköy Mental and Neurological Diseases Hospital, Ministry of Health of the Republic of Turkey

Intern Psychologist, Adolescent Psychiatry Clinic, Şişli Etfal Training and Research Hospital, Ministry of Health of the Republic of Turkey

### Academic achievements

Investigation of the Psychometric Properties of Mindful Attention Awareness Scale in a Group of Adolescents (2022-09-29) DOI: 10.4274/tjcamh.galenos.2021.79188

The Relationships Among Attachment Quality, Depressive Symptom Levels, and Metacognition Problems in Adolescents (2022-09-29) DOI:10.4274/tjcamh.galenos.2019.2018.07.022
